Description: ===== RATS is a short tool that performs a basic review of source code. It looks for security-related problems in the source code that you provide (see "Options" for what source code you can provide) and reports a few of the problems it finds. RATS is implemented as a Perl script. It is important to note that RATS currently only recognizes some common security issues, such as buffer overflows, and will not find all problems. Your source code must be free from buffer overflows and TOCTOU race conditions for the tool to work. 2. The scanning was written in Perl, but the program and database can be generated from any source code language you wish. However, the generation routine will likely assume that your source code is in C, C++, Perl, PHP or Python, so be sure to supply source code in that language. 3. There is no limit to the number of files you can supply for scanning. A list of all files selected can be given to the tool along with the code to be scanned by supplying RATS -FILE for each file. 4. It is best to use a tool like HTMLTAG to highlight the points of code to be reviewed with the RATS -FILE option. It does not do any scanning, but the code in the file is highlighted before RATS runs. 5. RATS is best run with the -options option. It requires a database to run, so it will need root privileges to access it. The -d database option will create the database that

RATS is a multi-platform utility which allows to audit source code for common security related programming errors, e.g. Buffer Overflows, Data Execution, Resource Exhaustion, etc. Moreover, the script can be used to find and highlight suspicious chunks of code that could give the attacker an opportunity to exploit the application. During the execution of RATS, it will generate a list of security defects and security-related heuristics warnings. Thanks to its multi-platform support, RATS can be used on your client, server, and cloud-based applications. There is a significant difference between RATS and most other tools. RATS tries to find more common types of flaws than other tools. For example, many tools will warn about String overflows. RATS will warn about Strings and re-use them in in-place assignments. It will not (yet) warn about re-use of arrays. Note: in RATS, re-use means passing the same value to a function or method more than once, such as with the += operator. When it finds re-use, RATS will typically also warn about these being logic errors, and that the memory is being re-initialized at every re-use, etc. Here are some of the functionality of RATS: -> Quick and dirty. RATS is not typically used to find security flaws, but it is a great tool for quick scans. RATS typically reports very high-level security-related issues. -> Find out about the application. Scan the code for common security-related issues. Look for re-use of common strings, including those stored in the database. Look for re-use of memory (assignments of strings and arrays to variables). Look for re-use of the database. Look for operations on a variable that is not checked. -> Audit variables. Find uninitialized strings, and strings not assigned to a variable. Find strings that are in-place assigned more than once. -> Audit API use. Identify if any of the API calls in your program can be exploited to gain information, or control, or access to other resources. -> Find incorrect errors. When you input incorrect values to a function, it will print out a message that includes the incorrect values, and it will also tell you where these incorrect values were used. -> Find skipped errors. For example, if you have a function that should not return a value, but it does, RATS will report this as a problem
